Induction heating is the process of heating an electrically conducting object by electromagnetic induction, through heat generated in the object by eddy currents. An induction heater consists of an electromagnet and an electronic oscillator that passes a high-frequency alternating current through the electromagnet. The rapidly alternating magnetic field penetrates the object, generating electric currents inside the conductor, called eddy currents. The eddy currents flowing through the resistance

Induction heating is a heat treating process that allows very targeted heating of metals by electromagnetic induction. The process relies on induced electrical currents within the material to produce heat and is the preferred method used to bond, harden or soften metals or other conductive materials. In modern manufacturing processes, this form of heat treatment offers a beneficial combination of speed, consistency and control.

Induction Heat Treating

Induction heating is a process which is used to bond, harden or soften metals or other conductive materials. For many modern manufacturing processes, induction heating offers an attractive combination of speed, consistency and control. The basic principles of induction heating have been understood and applied to manufacturing since the 1920s.

But with induction heating, heat is actually "induced" within the part itself by circulating electrical currents. Induction heating relies on the unique characteristics of radio frequency (RF) energy - that portion of the electromagnetic spectrum below infrared and microwave energy. Since heat is transferred to the product via electromagnetic waves, the part never comes into direct contact with any flame, the inductor itself does not get hot (see Figure 1), and there is no product contamination.

Induction Heating: What It Is, How it Works

Induction heating is a form of non-contact heating for conductive materials, when alternating current flows in the induced coil, varying electromagnetic field is set up around the coil, circulating current (induced, current, eddy current) is generated in the workpiece (conductive material), heat is produced as the eddy current flows against the resitivity of the material.

To ensure repeatability and efficiency in the induction heating application, the rod heating was completed as a pre-programmed process with specific, well-defined steps. At output power of 1.70 kW, it took mere 17 seconds for the heated part to achieve the target temperature of 148 ° C (300 ° F), at the required heat length of 3.5" (88.9mm).

The precise heating control available with induction is unmatched. Further, using the same heating fundamentals as vacuum crucible heating applications, induction heating can be carried under atmosphere for continuous applications. What is Induction? | Inductotherm Corp.

Induction heating is a very quick and precise process as heat is applied selectively only to parts of the workpiece where heat treatment is desired. Induction is generally suitable for all electrically conductive materials. Induction heating – the efficient way to accurately heat metals.

Power and control. Induction cooking provides fast heating, improved thermal efficiency, and more consistent heating than cooking by thermal conduction. Generally, the higher the power rating, the faster the cooking time. Induction cooktop power ratings are generally quoted for power delivered to the pan, whereas gas ratings are specified in terms of gas use, but gas is much less efficient.

Induction heating takes place in an electrically conducting object (not necessarily magnetic steel) when the object is placed in a varying magnetic field. Induction heating is due to the hysteresis and eddy-current losses. Hysteresis losses only occur in magnetic materials such as steel, nickel, and very few others.

Enhance your heating processes with induction heating. Heating processes can make or break production efficiency in any manufacturing vertical. Traditional heating process, such as flame, can cause inefficiencies and bottleneck production. Induction heating can be applied to a range of heating activities such as annealing, brazing, and forging.

Induction welding uses induction heating from radio frequency alternating current to magnetically excite an implant placed at the joint interface of the two parts being welded. This implant, or gasket, is normally a composite of the polymer to be welded with either metal fibers or ferromagnetic particles.
